

Distractor Strategy

You asked what strategy I used to generate distractor questions. Strictly speaking, these are distractor answer choices. The core strategy is misconception-first, not random-wrong.

Journey Checkpoints

- I authored distractors as plausible misunderstandings a learner might actually hold.
- Each wrong option targets a nearby distinction: mind vs model, training vs inference, context vs memory, probability vs truth, RAG vs training, diffusion vs autoregression.
- Feedback explains the misconception rather than simply saying the answer is wrong.
- Example: for What Is an LLM?, distractors include a conscious reader, a hand-written rulebook, and a search engine that knows every file.

Glossary Dojo

- The Dojo uses real glossary definitions/terms as distractors, so every wrong option still belongs to a real concept.
- It prioritizes explicitly confusable terms, related terms, shared concept clusters, same-stage terms, and learning-path-near terms.
- The engine tracks the represented term for each option so feedback can say, for example, "That definition is for X; the correct term is Y."
- Options are stably shuffled so the correct answer is not tied to A/B/C/D.

Why This Strategy Fits Prompt Life

- The app is teaching conceptual discrimination, not trivia recall.
- Good distractors should feel tempting for a specific reason, then reveal the boundary between two ideas.
- The tone stays calm: a wrong choice is treated as a useful diagnostic of a common mix-up.
